many, many others by Gahinet, Henrion, Bachelier, Chilali, Boyd, Balakrishnan, Galkowski and Rogers (2D systems) and others
Matlab® LMI Control Toolbox - in MATLAB 7 the LMI Control Toolbox has been incorporated into the Robust Control Toolbox

- Scilab LMI Toolbox
- SeDuMi (+ YALMIP)
- others (plenty of those released lately, indeed any SDP solver can be used to solve LMI)
Discrete-Time (DT) Linear Time-Invariant (LTI) System

\[ x_{k+1} = Ax_k, \quad x_0 = 0, \quad x_k \in \mathbb{R}^n \]  \quad (1)

The DTLTI system (1) is said to be **asymptotically stable** if

\[ \lim_{{k \to \infty}} x_k = 0, \quad \forall x_0 \neq 0 \]

The DTLTI system (1) is said to be stable **in the sense of Lyapunov** if there exists a Lyapunov function \( V(x) \) such that

\[ V(x_{k+1}) - V(x_k) < 0; \]
Stability

The following statements are equivalent:

- The system (1) is **asymptotically stable**.
- There exists a quadratic Lyapunov function
  \[ V(x) := x^T P x > 0, \quad P \in \mathbb{S}^n \]
  such that the system (1) is **stable in the sense of Lyapunov**.
- \[ \max_i \| \lambda_i(A) \| < 1. \]
Linear System Stability

Lyapunov Stability Test

Given the system (1) find if there exists a matrix $P \in \mathbb{S}^n$ such that

a) $V(x) := x^TPx > 0; \forall x \neq 0$

b) $V(x_{k+1}) - V(x_k) < 0; \forall x_{k+1} = Ax_k, x \neq 0$

Remarks

$V(x) := x^TPx > 0, \forall x \neq 0 \Rightarrow P > 0$  

$V(x_{k+1}) = x_{k+1}^TPx_{k+1} = x_k^TA^TPAx_k$

therefore

$V(x_{k+1}) - V(x_k) = x_k^TA^TPAx_k - x_k^TPx_k$

$V(x_{k+1}) - V(x_k) = x_k^T(A^TPA - P)x_k$

finally

$V(x_{k+1}) - V(x_k) < 0$ if, and only if $A^TPA - P < 0$
Lyapunov Stability Test

Given the system (1) find if there exists a matrix $P \in \mathbb{S}^n$ such that the LMI (Linear Matrix Inequality)

$$P > 0, \quad A^T PA - P < 0$$

is feasible

Note that there exist methods which allow us to solve the stability problem by direct and more effective methods, e.g.

- compute the eigenvalues of the matrix $A$
- solve the Lyapunov equality

$$P > 0, \quad A^T PA - P = -I$$
A linear matrix inequality (LMI) is an expression of the form (the canonical form)

\[ F(x) := F_0 + x_1 F_1 + \cdots + x_n F_n < 0 \]

where

- \( x = (x_1, \ldots, x_n) \) - vector of unknown scalar entries (decision variables)
- \( F_0, \ldots, F_n \) - known symmetric matrices
- \( < 0 \) - negative definiteness (in many publications \( \prec 0 \) for the matrix notation is used instead of \( < 0 \) - depends on you!)
LMIs have several intrinsic and attractive features

1. An LMI is convex constraint on \( x \) (a convex feasibility set). That is, the set \( S := \{ x : F(x) < 0 \} \) is convex. Indeed, if \( x_1, x_2 \in S \) and \( \alpha \in (0, 1) \) then

\[
F(\alpha x_1 + (1 - \alpha)x_2) = \alpha F(x_1) + (1 - \alpha)F(x_2) > 0
\]

where in the equality we used that \( F \) is affine and the inequality follows from the fact that \( \alpha \geq 0 \) and \( (1 - \alpha) \geq 0 \).

2. While the constraint is matrix inequality instead of a set of scalar inequalities like in linear programming (LP), a much wider class of feasibility sets can be considered.

3. Thirdly, the convex problems involving LMIs can be solved with powerful interior-point methods. In this case "solved" means that we can find the vector of the decision variables \( x \) that satisfies the LMI, or determine that no solution exists.
To confirm that the feasibility set represented by LMI is the convex set, the following inequality is now considered

\[
\begin{bmatrix}
1 & 0 & x_1 \\
0 & 1 & x_2 \\
x_1 & x_2 & 1
\end{bmatrix} = \begin{bmatrix}
1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix} + x_1 \begin{bmatrix}
0 & 0 & 1 \\
0 & 0 & 0 \\
1 & 0 & 0
\end{bmatrix} + x_2 \begin{bmatrix}
0 & 0 & 0 \\
0 & 0 & 1 \\
0 & 1 & 0
\end{bmatrix} > 0
\]

In this case, we see that the feasible set is the interior of the unit disc \((\sqrt{x_1^2 + x_2^2} \leq 1)\),
Note that the **Schur complement** (details will be given) of the block

\[
\begin{bmatrix}
1 & 0 \\
0 & 1
\end{bmatrix}
\]

in previous example gives the equivalent condition

\[
1 - \begin{bmatrix} x_1 & x_2 \end{bmatrix} \begin{bmatrix} 1 & 0 \\
0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\
x_2 \end{bmatrix} > 0 \iff 1 - (x_1^2 + x_2^2) > 0
\]
Other properties

\[ F(x) > 0 \text{ is equivalent to } -F(x) < 0 \]

\[ F(x) < G(x) \text{ is equivalent to } F(x) - G(x) < 0 \]

\[ F_1(x) < 0, \ F_2(x) < 0 \text{ is equivalent to } \text{diag}(F_1(x), F_2(x)) < 0 \]

\[ F(x) < 0, \ G(y) < 0 \text{ is equivalent to } \text{diag}(F_1(x), G(y)) < 0 \]
Example

Two convex sets described by the previous example and

\[ x_1 + 0.5 > 0 \]

are given. They can be expressed by the LMI of the form

\[
\begin{bmatrix}
1 & 0 & x_1 & 0 \\
0 & 1 & x_2 & 0 \\
x_1 & x_2 & 1 & 0 \\
0 & 0 & 0 & x_1 + 0.5
\end{bmatrix} > 0
\]

which represents the convex set depicted below (the intersection of hyperplane and the interior of the unit circle).
Consider the stability condition for continuous 1D system described by \( \dot{x}(t) = Ax(t) \), which states that the system is stable iff there exists a matrix \( P > 0 \) such that the LMI of \( A^T P + PA < 0 \) is satisfied. Assume that \( n = 2 \). To present it in the canonical form note that

\[
A = \begin{bmatrix}
a_{11} & a_{12} \\
a_{21} & a_{22}
\end{bmatrix}, \quad P = P^T = \begin{bmatrix}
p_{11} & p_{12} \\
p_{12} & p_{22}
\end{bmatrix}
\]

Next, the multiplication due to the structures of matrices \( A \) and \( P \) provides the following inequality (note that since \( a_{ij} \) and \( p_{kl} \) are scalars then \( a_{ij}p_{kl} = p_{kl}a_{ij} \))

\[
\begin{bmatrix}
2p_{11}a_{11} + 2p_{12}a_{21} & p_{12}(a_{11} + a_{22}) + p_{22}a_{21} + p_{11}a_{12} \\
p_{12}(a_{11} + a_{22}) + p_{22}a_{21} + p_{11}a_{12} & 2p_{12}a_{12} + 2p_{22}a_{22}
\end{bmatrix} < 0
\]

or write it in the canonical form as

\[
p_{11} \begin{bmatrix}
2a_{11} & a_{12} \\
a_{12} & 0
\end{bmatrix} + p_{12} \begin{bmatrix}
2a_{21} & a_{22} + a_{11} \\
a_{22} + a_{11} & 2a_{12}
\end{bmatrix} + p_{22} \begin{bmatrix}
0 & a_{21} \\
a_{21} & 2a_{22}
\end{bmatrix} < 0
\]
Numerical Solution: Interior-point Algorithm

• Basic idea
  ▶ Construct a barrier function \( \phi(x) \) that is well defined for strict feasible \( x \) and is \( -\varepsilon \) (where \( -\infty < \varepsilon \ll 0 \)) only at the optimal \( x = x^* \) e.g.
    \[
    \phi(x) = -\log \det (F(x)) = \log \det (F^{-1}(x))
    \]
  ▶ Generate a sequence \( \{x^{(k)}\} \) so that
    \[
    \lim_{k \to \infty} \phi(x^{(k)}) = -\gamma
    \]
  ▶ Stop if \( \phi(x^{(k)}) \) is negative enough

• polynomial-time algorithm - number of flops bounded by \( mn^3 \log (C/\epsilon) \) (for accuracy < \( \epsilon \))
  where \( m \) is row size of the LMI, \( n \) denotes number of decision variables and \( C \) is a scaling factor.

unconstrained optimization problem
\[
\min f(x) = \min f_0(x) + \mu \phi(x) = c^T x - \mu \log \det (F(x))
\]

Application of the Newton-like method
\[
H_k \Delta x_k = -t_k
\]
It can be shown that the LMI is equivalent to $n$ polynomial inequalities. To see consider the well-known result in matrix theory is positive definite if, and only if, all of its principal minors $m_i(x)$ are positive. This means that the principal minors are multivariate polynomials of indeterminates $x_i$ i.e.

\[
m_1(x) = F(x)_{11} = F_{011} + \sum_{i=1}^{n} x_i F_{i11}
\]

\[
m_2(x) = \det \left( \begin{bmatrix} F(x)_{11} & F(x)_{12} \\ F(x)_{21} & F(x)_{22} \end{bmatrix} \right) = \left( F_{011} + \sum_{i=1}^{n} x_i F_{i11} \right) \left( F_{022} + \sum_{i=1}^{n} x_i F_{i22} \right) - \left( F_{021} + \sum_{i=1}^{n} x_i F_{i21} \right) \left( F_{012} + \sum_{i=1}^{n} x_i F_{i12} \right)
\]
Analytic solution of the LMI problem - cont.

\[ m_k(x) = \det \begin{pmatrix} F(x)_{11} & \cdots & F(x)_{1k} \\ \vdots & \ddots & \vdots \\ F(x)_{k1} & \cdots & F(x)_{kk} \end{pmatrix} \]

\[ m_n(x) = \det(F(x)) = \det \begin{pmatrix} F(x)_{11} & \cdots & F(x)_{1n} \\ \vdots & \ddots & \vdots \\ F(x)_{n1} & \cdots & F(x)_{kn} \end{pmatrix} \]

where \( F(x)_{kl} \) denotes the element on \( k \)-th row and \( l \)-th column of \( F(x) \).
Consider again the problem of finding a block-diagonal matrix $P > 0$ ($P = \text{diag}(P_h, P_v)$) such that the following LMI

$$A^T PA - P < 0$$

or

$$- A^T PA + P > 0$$

is satisfied. Since $P = \text{diag}(x_1, x_2)$ and the matrix $A$ is given by

$$A = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix} = \begin{bmatrix} 0.4942 & 0.5706 \\ 0.1586 & 0.4662 \end{bmatrix}$$
The solution of the LMI (2) is equivalent to the solution of the set of inequalities

\[ m_1(x) = -x_1(a_{11}^2 - 1) - x_2 a_{21}^2 = 0.75576636x_1 - 0.02515396x_2 > 0 \]

\[ m_2(x) = -x_1(a_{11}^2 - 1) - x_2 a_{21}^2 = 0.32558436x_1 + 0.78265756x_2 > 0 \]

\[ m_3(x) = (-x_1(a_{11}^2 - 1) - x_2 a_{21}^2)(-x_1 a_{12}^2 - x_2(a_{22}^2 - 1)) \]
\[ -(-x_1 a_{12} a_{11} - x_2 a_{22} a_{21})(-x_1 a_{12} a_{11} - x_2 a_{22} a_{21}) \]
\[ = -0.32558436x_1^2 + 0.5579956166x_1 x_2 - 0.02515396x_2^2 > 0 \]

(3)

with

\[ x_1 > 0 \text{ and } x_2 > 0 \]  

(4)
On the other hand, recall that the LMI is a convex set in $\mathbb{R}^n$ defined as

$$\mathcal{F} = \left\{ x \in \mathbb{R}^n : F(x) = F_0 + \sum_{i=1}^{n} x_i F_i > 0 \right\}$$

which can be described in terms of principal minors as

$$\mathcal{F} = \{ x \in \mathbb{R}^n : m_i(x) \geq 0, \ i = 1, \ldots, n \}$$

Hence the inequalities (3) and (4) describe the convex set
To validate the result, computations for two points
\( p_1 = (x_1, x_2) = (2, 0.5) \) and \( p_2 = (x_1, x_2) = (0.5, 2) \) will be provided.
First consider the point \( p_1 \). In this case, the matrix below is obtained

\[
R = A^T P A - P = \begin{bmatrix}
-1.4990 & 0.6010 \\
0.6010 & 0.2598
\end{bmatrix}
\]

Because eigenvalues of the matrix \( R \) are \( \lambda_1 = -1.6847 \) and \( \lambda_2 = 0.4456 \), it is clear that \( p_1 \) is not the solution of the considered LMI (see that \( p_1 \) does not lie inside the feasible set). Taking \( p_2 \) into computation yields

\[
R = \begin{bmatrix}
-0.3276 & 0.2889 \\
0.2889 & -1.4025
\end{bmatrix}
\]

which is negative defined (its eigenvalues are \( \lambda_1 = -1.4752 \) and \( \lambda_2 = -0.2549 \)).
On the other hand, evaluating the principal minors (3) yields

<table>
<thead>
<tr>
<th></th>
<th>$p_1$</th>
<th>$p_2$</th>
</tr>
</thead>
<tbody>
<tr>
<td>$m_1(x)$</td>
<td>0.3759836866</td>
<td>0.3759836866</td>
</tr>
<tr>
<td>$m_2(x)$</td>
<td>-0.259839940</td>
<td>1.402522940</td>
</tr>
<tr>
<td>$m_3(x)$</td>
<td>1.498955740</td>
<td>0.327575260</td>
</tr>
</tbody>
</table>

These results clearly show that in the case of the point ($p_1$ not all principal minors are positive, hence we conclude again that this point does not solve the LMI).
The set of feasible solutions of considered LMI (the feasibility set) is denoted as follows

\[ \mathcal{F} = \left\{ x \in \mathbb{R}^M : F(x) = F_0 + \sum_{i=1}^{M} x_i F_i < 0 \right\} \]

Due to the fact that LMI is defined in the space of its decision variables \( (x \in \mathbb{R}^M) \) it is possible to present the feasibility set as a geometrical shape in this space.
For the **positive (non-negative)** definiteness of $F(x)$ it is required that all of its diagonal minors to be positive (non-negative). For the **negative (non-positive)** definiteness of $F(x)$ it is required that its diagonal minors of odd minors to be negative (non-positive) and the minors of even degree to be positive (non-negative) respectively.

It is straightforward to see that the diagonal minors are multi-variable polynomials of variables $x_i$. So the LMI set can be described as

$$
\mathcal{F}(x) = \{ x \in \mathbb{R}^M : f_i(x) > 0, \ i = 1, \ldots, M \}
$$

which is a semi-algebraic set. Moreover, it is a convex set.
\[
F(x_1, x_2) = \begin{bmatrix}
  x_1 - 4 & -x_2 + 2 & 0 \\
  -x_2 + 2 & -1 & x_1 - x_2 \\
  0 & x_1 - x_2 & -x_1 - 1
\end{bmatrix} < 0
\]

To find the feasibility region of the above LMI write the conditions for the diagonal minors of degree: first, second and third in variables \( x_1, x_2 \). So the minors become

\[
\begin{align*}
\begin{cases}
  x_1 - 4 < 0 \\
  -1 < 0 \\
  -x_1 - 1 < 0
\end{cases} & \text{first degree minors} \\
\begin{cases}
  -(x_1 - 4) - (-x_2 + 2)^2 > 0 \\
  -(x_1 - 1) - (x_1 - x_2)^2 > 0 \\
  (x_1 - 4)(-x_1 - 1) > 0
\end{cases} & \text{- must be negative} \\
\begin{cases}
  -(x_1 - 4)(-x_1 - 1) \\
  -(x_2 - 2)^2(-x_1 - 1) \\
  -(x_1 - 4)(x_1 - x_2)^2 < 0
\end{cases} & \text{second degree minors} \\
\begin{cases}
  -(x_1 - 4)(-x_1 - 1) \\
  -(x_2 - 2)^2(-x_1 - 1) \\
  -(x_1 - 4)(x_1 - x_2)^2 < 0
\end{cases} & \text{third degree minor (\( \det F(x) \))}
\end{align*}
\]
Figure: The solutions for the first (a) and second (b) degree minors

Figure: The solutions for the third (a) degree minors and the feasibility region for the considered LMI (b)
**Conclusion**

It is straightforward to see that the feasibility region is the $\bigcap$ of the regions which satisfy the constrains due to corresponding minors.
Matlab solution (script test0.m provides \( x_1 = 1.6667, \)
\( x_2 = 1.8333 \)). Refer to the figure

**Figure**: The feasibility region and the Matlab solution
Consider the linear time-invariant system with one control input $u_k$ in the form

$$x_{k+1} = Ax_k + Bu_k, \quad x_0 = 0, \quad x_k \in \mathbb{R}^n, \quad u_k \in \mathbb{R}^m$$

connected in feedback with the state feedback controller

$$u_k = Kx_k$$

This arrangement produces the following closed-loop system

$$x_{k+1} = (A + BK)x_k$$
The considered system can be tested for asymptotic stability using the Lyapunov method for any given controller $K$.

as the result we have the following inequality

$$P > 0, \quad (A + BK)^T P (A + BK) - P < 0$$

or (for differential system)

$$P > 0, \quad (A + BK)^T P + P (A + BK) < 0$$

where $P$ and $K$ are variables (they are unknown).

Unfortunately, one can easily show that the resulting inequalities are not jointly convex on $P$ and $K$. 
Bilinear Matrix Inequality (BMI) has the following form

\[ F(x, y) = F(x, y)^T = F_0 + \sum_{i=1}^{n} x_i F_i + \sum_{j=1}^{m} y_j G_j + \sum_{i=1}^{n} \sum_{j=1}^{m} x_i y_j H_{ij} < 0 \]

where

- \( x = (x_1, \ldots, x_n), x \in \mathbb{R}^n \) and \( y = (x_1, \ldots, y_m), y \in \mathbb{R}^m \) are the variables

- symmetric matrices \( F_0, F_i, i = 1, \ldots, n, G_j, j = 1, \ldots, m \) and \( H_{ij}, i = 1, \ldots, n, j = 1, \ldots, m \) are given data.

**Remark**

Unfortunately, BMIs are in general highly non-convex optimization problems, which can have multiple local solutions, hence solving a general BMI was shown to be \( \mathcal{NP} \)-hard problem.
Consider the following bilinear inequality

\[ 1 - xy > 0 \]  

(5)

It is clear that (5) does not represent a convex set. To see this, consider two points on \( xy \)-plane which satisfy (5), e.g. \( p_1 = (x_1, y_1) = (0.2, 2) \) and \( p_2 = (x_2, y_2) = (4, 0.2) \).

Obviously, the point in the half way between the two values, i.e.

\[ p_3 = \frac{1}{2} (0.2, 2) + \frac{1}{2} (4, 0.2) = (2.1, 1.1) \]

does not satisfy (5).
Can BMIs be written in the form of LMIs?

- Consider the following BMI

\[
\begin{bmatrix}
  x_2(-13 - 5x_1 + x_2) & x_2 & 0 \\
  x_2 & x_1 & 0 \\
  0 & 0 & x_1(-13 - 5x_1 + x_2) - x_2
\end{bmatrix} > 0
\]

- feasibility set is \textit{convex}!

- the LMI form can be obtained

\[
\begin{bmatrix}
  -1 + x_1 & 1 \\
  1 & -1 - \frac{5}{18}x_1 + \frac{1}{18}x_2
\end{bmatrix} > 0
\]
If some matrix $F(x)$ is positive defined than $z^T F(x) z > 0$, $\forall z \neq 0$, $z \in \mathbb{R}^n$. Assume now that $z = M y$ where $M$ is any given nonsingular matrix, hence

\[
z^T F(x) z > 0
\]

implies that

\[
y^T M^T F(x) M y > 0
\]

This means that some rearrangements of the matrix elements do not change the feasible set of LMIs.
Methods to reformulate hard problems into LMIs

If the following LMI is feasible

\[
\begin{bmatrix}
  A & B \\
  C & D
\end{bmatrix} < 0
\]

then immediately the following LMI is feasible too

\[
\begin{bmatrix}
  D & C \\
  B & A
\end{bmatrix} < 0
\]

where

\[
\begin{bmatrix}
  D & C \\
  B & A
\end{bmatrix} = \begin{bmatrix}
  0 & I \\
  I & 0
\end{bmatrix} \begin{bmatrix}
  A & B \\
  C & D
\end{bmatrix} \begin{bmatrix}
  0 & I \\
  I & 0
\end{bmatrix}
\]
In the case of the Lyapunov inequalities, the fact that the nice inequalities previously obtained are functions of $X := P^{-1}$, and not $P$, suggests that we might start by rewriting the inequalities in terms of $X$.

$$X > 0, \quad X(A + BK)^T + (A + BK)X < 0$$

We then manipulate the second inequality by expanding the products

$$AX + XA^T + BKX + XK^TB^T < 0.$$
introduce the new unknown $N = KX$

to eliminate the matrix $K$, or, in other words, $K$ can be explicitly expressed in terms of other unknowns, by solving the change of variable equation for the unknown $K$. This produces $K = LX^{-1}$

finally, we have to solve the following inequality

$$X > 0, \quad AX + XA^T + BL + L^T B^T < 0,$$
Methods to reformulate hard problems into LMIs
Schur complement formula

Quadratic but convex inequality can be converted into the LMI form using the Schur complement formula given by the following Lemma.

Let \( A \in \mathbb{R}^{n \times n} \) and \( C \in \mathbb{R}^{m \times m} \) be symmetric matrices and \( A \succ 0 \) then

\[
C + B^T A^{-1} B < 0
\]

if and only if

\[
U = \begin{bmatrix}
-A & B \\
B^T & C
\end{bmatrix} < 0 \quad \text{or, equivalently,} \quad U = \begin{bmatrix}
C & B^T \\
B & -A
\end{bmatrix} < 0
\]

The matrix \( C + B^T A^{-1} B \) is called the Schur complement of \( A \) in \( U \). The identical result holds for a positive defined case.
Consider a controller design for discrete LRPs. It can be shown that the following LMI gives sufficient condition for stability along the pass

\[(\Phi + RK)^T W (\Phi + RK) - W < 0\]  

(6)

where \( W > 0 \) is block-diagonal matrix variable, \( \Phi \) and \( R \) are given matrices identified in process state-space model as

\[
\Phi = \begin{bmatrix} A & B_0 \\ C & D_0 \end{bmatrix}, \quad R = \begin{bmatrix} B & 0 \\ 0 & D \end{bmatrix}
\]

and

\[
K = \begin{bmatrix} K_1 & K_2 \\ K_1 & K_2 \end{bmatrix}
\]

is the matrix to be found.
Applying the Schur complement formula to (6) yields

\[
\begin{bmatrix}
  -W^{-1} & \Phi + RK \\
  \Phi^T + K^T R^T & -W
\end{bmatrix} < 0
\]

The above form is still nonlinear due to the occurrence of terms $W^{-1}$ and $W$ (hence it can be stated in terms of BMI). To overcome this problem, introduce the substitution $P = W^{-1}$ and then multiply the result from the left and the right by diag($I$, $P$) to obtain

\[
\begin{bmatrix}
  -P & \Phi P + RN \\
  P\Phi^T + N^T R^T & -P
\end{bmatrix} < 0
\]

(7)

where $N = KP$. Now, it is straightforward to see that (7) is numerically solvable.
In robustness analysis, we often encounter the following terms

\[ HFE + E^T F^T H^T \]  \hspace{1cm} (8)

where \( H, E \) are known real matrices of appropriate dimensions, and the matrix \( F \) represents parameter uncertainties which satisfies

\[ F^T F \leq I \text{ or equivalently } \| F \| \leq 1 \]

Inequalities which consist of (8) can be transformed into the LMI with the following Lemma

**Lemma**

*Let \( H, E \) be given real matrices of appropriate dimensions and \( F \) satisfy \( F^T F \leq I \). Then for any \( \epsilon > 0 \) the following holds*

\[ HFE + E^T F^T H^T \leq \epsilon HH^T + \frac{1}{\epsilon} E^T E \]
Since it is true that
\[
\left( \epsilon \frac{1}{2} H^T - \epsilon^{-\frac{1}{2}} F E \right)^T \left( \epsilon \frac{1}{2} H^T - \epsilon^{-\frac{1}{2}} F E \right) \geq 0
\]
then expansion of the above yields
\[
\epsilon^{-1} E^T F^T F E + \epsilon H H^T \geq H F E + E^T F^T H^T
\]
Next, observe that
\[
\| F \| \leq 1 \Leftrightarrow \lambda_{\text{max}}(F^T F) \leq 1 \Leftrightarrow F^T F \geq I
\]
hence
\[
\epsilon H H^T + \frac{1}{\epsilon} E^T E \geq \epsilon^{-1} E^T F^T F E + \epsilon H H^T \geq H F E + E^T F^T H^T
\]
and the proof is complete.
For certain specific matrix inequalities, it is often possible to eliminate some of the matrix variables.

**Lemma**

Let $\Psi \in \mathbb{R}^{q \times q}$ be a symmetric matrix and $P \in \mathbb{R}^{r \times q}$ and $Q \in \mathbb{R}^{s \times q}$ be real matrices then there exists a matrix $\Theta \in \mathbb{R}^{r \times s}$ such that

$$
\Psi + P^T \Theta^T Q + Q^T \Theta P < 0
$$

if and only if the inequalities

$$
\mathcal{W}_P^T \Psi \mathcal{W}_P < 0 \text{ and } \mathcal{W}_Q^T \Psi \mathcal{W}_Q < 0
$$

both hold, where $\mathcal{W}_P$ and $\mathcal{W}_Q$ are full rank matrices satisfying

$\text{Im}(\mathcal{W}_P) = \ker(P)$ and $\text{Im}(\mathcal{W}_Q) = \ker(Q)$

It can also be used to eliminate variables from already formulated LMI. Since some variables can be eliminated, the computation burden can be reduced greatly.
Elimination of variables - an example

Consider again the stabilisation problem. The right-hand term can be rewritten as

\[
\begin{bmatrix}
PΦT + N^TR^T & ΦP + RN \\
ΦP + RN & -P
\end{bmatrix}
\begin{bmatrix}
PΦT + N^TR^T & ΦP + RN \\
ΦP + RN & -P
\end{bmatrix}
= \begin{bmatrix}
-P & ΦP \\
PΦT & -P
\end{bmatrix}
+ \begin{bmatrix}
R \\
0
\end{bmatrix}
N\begin{bmatrix}
0 & \text{I}
\end{bmatrix}
+ \begin{bmatrix}
0 & \text{I}
\end{bmatrix}
N^T\begin{bmatrix}
R^T & 0
\end{bmatrix}
\]

Using Elimination of Variables Lemma, we obtain

\[
\mathcal{W}_R^T\begin{bmatrix}
PΦT & ΦP \\
PΦT & -P
\end{bmatrix}
\mathcal{W}_R < 0, \quad \mathcal{W}_S^T\begin{bmatrix}
PΦT & ΦP \\
PΦT & -P
\end{bmatrix}
\mathcal{W}_S < 0
\]

where \( \mathcal{W}_R = \text{diag}(\text{ker}(R), \text{I}) \) and \( \mathcal{W}_S = \text{diag}(\text{I}, \text{0}) \). These two LMI conditions can be checked with less computation burden than the LMI condition provided in the Schur Complement example.
Illustrative computations have been performed for processes of prescribed order \( (n) \) and the results are listed in the below Table.

Note that all computations have been performed with LMI Control Toolbox 1.0.8 under MATLAB 6.5. The MATLAB-files have been run on a PC with AMD Duron 600 MHz CPU and 128MB RAM.
The discrete system state-space equation

\[ x_{k+1} = Ax_k + Bu_k \]

Lyapunov inequality for discrete system

\[ A^TPA - P < 0, \ P > 0 \]

Controller design:
The closed loop for the discrete case \( u_k = Kx_k \) (\( K \) is the controller to be designed)

The stabilization condition for the discrete case

\[ (A + BK)^TP(A + BK) - P < 0, \ P > 0 \]

not the LMI condition since the variable matrices are multiplied
It requires some operations

1. The stabilization condition for the discrete case
   \[(A + BK)^T P (A + BK) - P < 0, \ P > 0\] - not the LMI condition since the variable matrices are multiplied

2. Schur complement to get
   \[
   \begin{bmatrix}
   -P & A^T + K^T B^T \\
   A + BK & -P^{-1}
   \end{bmatrix} < 0, \ P > 0
   \]

3. Left- and right- multiplication by \(\text{diag}(P^{-1}, I)\) and set \(Q = P^{-1}\)
   \[
   \begin{bmatrix}
   -Q & QA^T + QK^T B^T \\
   AQ + BKQ & -Q
   \end{bmatrix} < 0, \ Q > 0
   \]

4. Setting \(K = NQ^{-1}\) to obtain finally the LMI
   \[
   \begin{bmatrix}
   -Q & QA^T + N^T B^T \\
   AQ + BN & -Q
   \end{bmatrix} < 0, \ Q > 0
   \]
1D differential system state-space equation \( \dot{x}(t) = Ax(t) + Bu(t) \)

Lyapunov inequality for 1D differential system \( A^T P + PA < 0, \ P > 0 \)

Controller design

The closed loop for the different case \( u(t) = Kx(t) \)

The stabilization condition for the differential case

\( (A + BK)^T P + P(A + BK) < 0, \ P > 0 \) - not the LMI condition
Operations

1. the closed loop Lyapunov inequality

\[
(A + BK)^T P + P(A + BK) < 0, \ P > 0
\]

2. the congruence transformation (left- and right- multiplication) by \( P^{-1} \) to get

\[
P^{-1}(A + BK)^T + (A + BK)P^{-1} < 0, \ P^{-1} > 0
\]

3. set \( Q = P^{-1} \)

\[
QA + QK^T B^T + AQ + BKQ < 0, \ Q > 0
\]

4. finally set \( K = NQ^{-1} \) to obtain the following LMI

\[
QA + N^T B^T + AQ + BN < 0, \ Q > 0
\]
The LMI software can solve the LMI problems formulated in three different forms:

- feasibility problem,
- linear optimization problem,
- generalized eigenvalue minimization problem.
A feasibility problem is defined as follows

**Definition**
Find a solution $x = (x_1, \ldots, x_n)$ such that

$$F(x) > 0 \quad (9)$$

or determine that the LMI (9) is infeasible.

A typical situation for the feasibility problem is a stability problem where one has to decide if a system is stable or not (an LMI is feasible or not).
Linear objective minimization problem

**Definition**
Minimize a linear function $c^T x$ ($x = (x_1, \ldots, x_n)$), where $c \in \mathbb{R}^n$ is a given vector, subject to an LMI constraint (9) or determine that the constraint is infeasible. Thus the problem can be written as

$$\min c^T x$$
$$\text{subject to } F(x) > 0$$

This problem can appear in the equivalent form of minimizing the maximum eigenvalue of a matrix that depends affinely on the variable $x$, subject to an LMI constraint (this is often called EVP)

$$\min \lambda$$
$$\text{subject to } \lambda I - F(x) > 0$$
The generalized eigenvalue problem (GEVP) allows us to minimize the maximum generalized eigenvalue of a pair of matrices that depend affinely on the variable $x = (x_1, \ldots, x_n)$. The general form of GEVP is stated as follows

$$\min \lambda$$

subject to

$$\begin{align*}
A(x) &< \lambda B(x) \\
B(x) &> 0 \\
C(x) &< D(x)
\end{align*}$$

(10)

where $C(x) < D(x)$ and $A(x) < \lambda B(x)$ denote set of LMIs. It is necessary to distinguish between the standard LMI constraint, i.e.

$$C(x) < D(x)$$

and the LMI involving $\lambda$ (called the linear-fractional LMI constraint)

$$A(x) < \lambda B(x)$$

which is quasi-convex with respect to the parameters $x$ and $\lambda$. However, this problem can be solved by similar techniques as those for previous problems.
A system matrix $A$ has a stability margin $q$, iff the stability condition holds for $(1 + q)A$.

So, it is straightforward to get the LMI conditions to check if $A$ has a’priori defined $q$. It is also easy to write the appropriate condition for computing the controller $K$ providing the required $q$ in the closed loop.
In our case (1D discrete case considered) we have the following LMI condition

\[
\begin{bmatrix}
-Q & (1 + q)(QA^T + N^TB^T) \\
(1 + q)(AQ + BN) & -Q
\end{bmatrix} < 0, \quad Q > 0
\]

\[K = NQ^{-1}\]

**Remark**

Note that \((1 + q)\) is a scalar, so for any matrix, say \(T\), holds

\[(1 + q)T = T(1 + q)\]

To get the GEVP condition, the follow the steps (on the next slide)
\[
\begin{bmatrix}
-Q & QA^T + N^T B^T \\
AQ + BN & -Q
\end{bmatrix} < q (\begin{bmatrix}
0 & QA^T + N^T B^T \\
AQ + BN & 0
\end{bmatrix}) \quad Q > 0
\]

Multiply it by \(q^{-1}\) (positive since \(q > 0\)) and set \(\lambda = q^{-1}\) and then by \(-1\) to obtain

\[
\begin{bmatrix}
0 & QA^T + N^T B^T \\
AQ + BN & 0
\end{bmatrix} < \lambda \begin{bmatrix}
Q & -QA^T - N^T B^T \\
-AQ - BN & Q
\end{bmatrix} \quad Q > 0
\]

Write it as the GEVP

\[
\begin{aligned}
\min \lambda \text{ s.t.} \quad & \left\{ \begin{bmatrix}
0 & QA^T + N^T B^T \\
AQ + BN & 0
\end{bmatrix} < \lambda \begin{bmatrix}
Q & -QA^T - N^T B^T \\
-AQ - BN & Q
\end{bmatrix} \\
& \begin{bmatrix}
-Q & QA^T + N^T B^T \\
AQ + BN & -Q
\end{bmatrix} < 0
\end{aligned}
\]

\[
K = NQ^{-1}, \quad q = \lambda^{-1}
\]

Note that the additional constraint is just the stability condition in this case.

LMI region is any subset $\mathcal{D}$ of the complex plane that can be defined as

$$\mathcal{D} = \{z \in \mathbb{C} : L + zM + \bar{z}M^T < 0\} \quad (\%)$$

where $L$ and $M$ are real matrices and $L = L^T$

The matrix-valued function

$$f_{\mathcal{D}}(z) = L + zM + \bar{z}M^T$$

is called the characteristic function of $\mathcal{D}$
A real matrix $A$ is $\mathcal{D}$-stable, i.e. has all eigenvalues inside the $\mathcal{D}$ region iff there exists a symmetric matrix $X > 0$ such that the following LMI holds

$$L \otimes X + M \otimes (XA) + M^T \otimes (A^T M) < 0 \quad ($$)

where $\otimes$ denotes the Kronecker product.

**Very important result !!!** - indeed, this generalizes all we said about the stability.
Common known $\mathcal{D}$ regions

- half-plane $\Re(z) < -\alpha : z + \bar{z} + 2\alpha < 0$
- special case of the above i.e. $\Re(z) < 0 : z + \bar{z} < 0$ - the stability region for the differential system described by $A$
- disc centered at $(-q, 0)$ with radius $r$

\[
\begin{bmatrix}
-r & q + z \\
q + \bar{z} - r & \bar{z}
\end{bmatrix} < 0
\]

- ellipse centered at $(-q, 0)$ with radiuses $a$-horizontal and $b$-vertical

\[
\begin{bmatrix}
-2a & -2(1 + a/b) & -2a \\
-2(1 - a/b) & -2(1 + a/b) & -2a \\
-2(1 - a/b) & -2(1 + a/b) & -2a
\end{bmatrix} + z\begin{bmatrix}
0 & (1 + a/b) \\
(1 - a/b) & 0
\end{bmatrix} + \bar{z}\begin{bmatrix}
0 & (1 - a/b) \\
(1 + a/b) & 0
\end{bmatrix} = L + zM + \bar{z}M^T < 0
\]

- conic sector with apex at the origin and inner angle (see reference)
- any intersection(s) of the above
Note, that it is now easy to find the LMI condition which checks, if matrix eigenvalues lay inside chosen region - **weak?** Yes, but ... Instead of \( A \) write it in the closed loop configuration i.e. \( A + BK \) - we get the way to drive \( A \) to have eigenvalues inside chosen region using controller \( K \)- **strong enough!**

So, the procedure is as follows

- choose \( D \)
- write it as LMI region (%)
- write ($)
- use some linear algebra operations to get programmable LMI
- solve it using your favorite software
1. choose ellipse

\[
\begin{bmatrix}
-2a & -2g \\
-2g & -2a
\end{bmatrix} + z \begin{bmatrix}
0 & (1 + a/b) \\
(1 - a/b) & 0
\end{bmatrix} + \bar{z} \begin{bmatrix}
0 & (1 - a/b) \\
(1 + a/b) & 0
\end{bmatrix} = L + zM + \bar{z}M^T < 0
\]

2. set \( \mathcal{A} = \mathbf{A} + \mathbf{BK} \)

3. condition for the closed loop system

\[
L \otimes X + M \otimes (X\mathcal{A}) + M^T \otimes (\mathcal{A}^T X) < 0
\]

which can be rewritten as

\[
\begin{bmatrix}
-2aX \\
-2gX + (1 + \frac{a}{b})\mathbf{A}^T X + (1 - \frac{a}{b})X\mathbf{A} & (\ast) \\
-2gX + (1 + \frac{a}{b})(\mathbf{A} + \mathbf{BK})^T X + (1 - \frac{a}{b})X(\mathbf{A} + \mathbf{BK}) & -2aX
\end{bmatrix} < 0
\]

4. set \( \mathcal{A} = \mathbf{A} + \mathbf{BK} \) to obtain

\[
\begin{bmatrix}
-2aX \\
-2gX + (1 + \frac{a}{b})(\mathbf{A} + \mathbf{BK})^T X + (1 - \frac{a}{b})X(\mathbf{A} + \mathbf{BK}) & (\ast) \\
-2gX + (1 + \frac{a}{b})(\mathbf{A} + \mathbf{BK})^T X + (1 - \frac{a}{b})X(\mathbf{A} + \mathbf{BK}) & -2aX
\end{bmatrix} < 0
\]

not LMI - again \( X \) and \( K \) multiplied
5 Pre and post multiply it by \( \text{diag}(X^{-1}, X^{-1}) \) and set \( Y = X^{-1} \) to obtain
\[
\begin{bmatrix}
-2aY \\
-2gY + (1 + \frac{a}{b})YA^T + YK^TB^T + (1 - \frac{a}{b})AY + BKY & -2aY 
\end{bmatrix} < 0
\]
which still isn’t the LMI

6 set \( K = NY^{-1} \) to obtain the LMI
\[
\begin{bmatrix}
-2aY \\
-2gY + (1 + \frac{a}{b})YA^T + N^TB^T + (1 - \frac{a}{b})AY + BN & -2aY 
\end{bmatrix} < 0
\]
DTLTI Uncertain system

\[ x_{k+1} = Ax_k, \quad x_0 = 0, \quad x_k \in \mathbb{R}^n, \quad A \in \mathcal{A} \]

where \( \mathcal{A} \) is an arbitrary closed convex set

Robust Stability
The DTLTI uncertain system is said to be robustly stable if it is asymptotically stable for all \( A \in \mathcal{A} \).

Problem
The set of all (discrete-time) stable matrices is not a convex set.
Let us consider a set formed from 2 vertices and assume that they are

\[ A_1 = \begin{bmatrix} 0.5 & 2 \\ 0 & 0.5 \end{bmatrix}, \quad A_2 = \begin{bmatrix} 0.5 & 0 \\ 2 & 0.5 \end{bmatrix} \]

Based on well known fact that stability in the discrete case is guaranteed if and only if all eigenvalues of a system matrix lie in the interior of the unit circle, it can be seen that the matrices \( A_1 \) and \( A_2 \) are stable (\( \lambda_{\text{max}}(A_1) = 0.5 \) and \( \lambda_{\text{max}}(A_2) = 0.5 \)). However, a convex combination yields

\[ A = 0.5A_1 + 0.5A_2 = \begin{bmatrix} 0.5 & 1 \\ 1 & 0.5 \end{bmatrix} \]

and \( \lambda_{\text{max}}(A) = 1.5 \). This means that \( A \) is unstable.
Two main models of uncertainty

- norm-bounded
- polytopic
- affine
Norm-bounded model of uncertainty.

This model of uncertainty corresponds to a system which matrices uncertainty are modelled as an **additive perturbation** to the nominal system matrices. Therefore a system is said to be subjected to norm-bounded parameter uncertainty if matrices of such a system can be written in the form

\[ \mathbf{M} = \mathbf{M}_0 + \Delta \mathbf{M} = \mathbf{M}_0 + \mathbf{H} \mathbf{F} \mathbf{E} \]

where \( \mathbf{H} \) and \( \mathbf{E} \) are some known constant matrices with compatible dimensions and \( \mathbf{M}_0 \) defines the nominal system. \( \mathbf{F} \) is an unknown, constant matrix which satisfies

\[ \mathbf{F}^T \mathbf{F} \leq \mathbf{I} \]
Important: The inequality

$$\mathcal{F}^T \mathcal{F} \leq I$$

represents a convex set. To see this, apply the Schur complement formula to obtain

$$\mathcal{F}^T \mathcal{F} \leq I \iff \begin{bmatrix} I & \mathcal{F} \\ \mathcal{F}^T & I \end{bmatrix} \geq 0$$
This model of uncertainty corresponds to a system which matrices range in the **polytope of matrices**. This means that each system matrix $M$ is only known to lie in a given fix polytope of matrices described by

$$M \in \text{Co}(M_1, M_2, \ldots, M_h)$$

where $\text{Co}$ denotes the convex hull. Then, for positive $i = 1, 2, \ldots, h$, $M$ can be written as

$$M := \left\{ X : X = \sum_{i=1}^{h} \alpha_i M_i, \quad \alpha_i \geq 0, \quad \sum_{i=1}^{h} \alpha_i = 1 \right\}$$
As a simple example, the polytope formed from 4 vertices: $M_1, M_2, M_3$ and $M_4$ is depicted below.

**Figure:** A polytope
Affine model of uncertainty

This model of uncertainty corresponds to a system which matrices are modelled as a collection of fixed affine functions of some varying parameters $p_1, \ldots, p_k$ i.e. each matrix can be written in the form

$$M(p) = M_0 + p_1M_1 + \ldots + p_kM_k$$

(11)

where $M_i; \forall i = 0, 1, \ldots, k$ are given. Parameter uncertainty is described with range of parameter values. It means that each parameter $p_i$ ranges between two known extremal values $\underline{p}_i$ (minimum) and $\overline{p}_i$ (maximum), therefore it can be written as

$$\underline{p}_i \leq p_i \leq \overline{p}_i$$

Furthermore, the set of uncertain parameters is

$$\Delta \triangleq \{p=(p_1, p_2, \ldots, p_k) : \underline{p}_i \leq p_i \leq \overline{p}_i, \ i=1, \ldots, k\}$$

and the set of corners of uncertainty region $\Delta_0$ is defined as

$$\Delta_0 \triangleq \{p=(p_1, p_2, \ldots, p_k) : p \in \{\underline{p}_i, \overline{p}_i\}, \ i=1, \ldots, k\}$$
Affine model of uncertainty

As an example of a set of uncertain parameters, consider 3 parameters: $p_1, p_2, p_3$ whose values range in the parameter box formed by their extremal values in 3-D parameter space.

**Figure:** 3-D parameter space
Form affine parameter-dependent matrices to the polytopic form

It is clear that $\mathbf{M}(\mathbf{p})$ is an affine function in $\mathbf{p} = (p_1, p_2, \ldots, p_k)$, thus it maps these corners to the polytope of vertices. In this case each vertex can be determined $\forall \mathbf{p} \in \Delta_0$ with the formula below

$$\mathbf{M}_i = \mathbf{M}_0 + p_1 \mathbf{M}_1 + \ldots + p_k \mathbf{M}_k$$

where $i = 1, \ldots, 2^k$. 

---

Figure: Transformation from the affine model to the polytopic model
Norm-bounded uncertainty

The system plant $\Phi := \begin{bmatrix} A & B \\ C & D \end{bmatrix}$

Uncertainties $\Delta \Phi := \begin{bmatrix} \Delta A & \Delta B \\ \Delta C & \Delta D \end{bmatrix} = \begin{bmatrix} H_1 \\ H_2 \end{bmatrix} F(k) \begin{bmatrix} E_1 \\ E_2 \end{bmatrix}$ and $\|F(k)\| < 1$

The uncertain system plant matrix $\Phi + \Delta \Phi$
Norm-bounded uncertainty

Discrete case - controller design (so we want to get the condition for computing $K$)

▶ For simplicity take $F(k) = F$ - no loose of generalization
▶ The Lyapunov inequality for the closed loop uncertain system

$$(A + H_1F_1 + BK + H_1F_2K)^TP(A + H_1F_1 + BK + H_1F_2K) - P < 0, \ P > 0$$

▶ Schur complement

$$\begin{bmatrix}
-P & A^T + E_1^TF_1^TH_1^T + K^TB^T + K^TE_2^TF_1^TH_1^T \\
A + H_1F_1 + BK + H_1F_2K & -P^{-1}
\end{bmatrix} < 0, \ P > 0$$

▶ write it as

$$\begin{bmatrix}
-P & A^T + K^TB^T \\
A + BK & -P^{-1}
\end{bmatrix} + \begin{bmatrix}
0 & E_1^TF_1^TH_1^T + K^TE_2^TF_1^TH_1^T \\
H_1F_1 + H_1F_2K & 0
\end{bmatrix} < 0, \ P > 0$$
or

\[
\begin{bmatrix}
-P & A^T + K^T B^T \\
A + BK & -P^{-1}
\end{bmatrix}
+ \begin{bmatrix}
E_1^T + K^T E_2^T \\
0
\end{bmatrix}
\begin{bmatrix}
F^T \\
0
\end{bmatrix}
+ \begin{bmatrix}
0 \\
H_1
\end{bmatrix}
\begin{bmatrix}
F \\
E_1 + E_2 K
\end{bmatrix}
< 0, \quad P > 0
\]

apply Lemma 2 to obtain

\[
\begin{bmatrix}
-P & A^T + K^T B^T \\
A + BK & -P^{-1}
\end{bmatrix}
+ \epsilon^{-1} \begin{bmatrix}
E_1^T + K^T E_2^T \\
0
\end{bmatrix}
\begin{bmatrix}
E_1 + E_2 K \\
0
\end{bmatrix}
+ \epsilon \begin{bmatrix}
0 \\
H_1
\end{bmatrix}
\begin{bmatrix}
0 \\
H_1^T
\end{bmatrix}
< 0, \quad P > 0, \quad \epsilon > 0
\]
write it as (since $\epsilon$ is a scalar)

$$
\begin{bmatrix}
-P & A^T + K^T B^T \\
A + BK & -P^{-1}
\end{bmatrix}
+ \begin{bmatrix}
E_1^T + K^T E_2^T \\
\epsilon H_1
\end{bmatrix}
\begin{bmatrix}
\epsilon^{-1} I \\
E_1 + E_2 K
\end{bmatrix}
< 0, \quad P > 0, \quad \epsilon > 0
$$

Apply the Schur complement again

$$
\begin{bmatrix}
-P & A^T + K^T B^T \\
A + BK & -P^{-1} \\
E_1 + E_2 K & \epsilon H_1^T
\end{bmatrix}
< 0, \quad P > 0, \quad \epsilon > 0
$$

still not the LMI

congruence by $\text{diag}(P^{-1}, I, I)$ and set $Q = P^{-1}$

$$
\begin{bmatrix}
-Q & QA^T + QK^T B^T & QE_1^T + QK^T E_2^T \\
A Q + BK Q & -Q & \epsilon H_1 \\
E_1 Q + E_2 K Q & \epsilon H_1^T & -\epsilon I
\end{bmatrix}
< 0, \quad Q > 0, \quad \epsilon > 0
$$

finally set $K = N Q^{-1}$ to obtain the LMI

$$
\begin{bmatrix}
-Q & QA^T + N^T B^T & QE_1^T + N^T E_2^T \\
A Q + BN & -Q & \epsilon H_1 \\
E_1 Q + E_2 N & \epsilon H_1^T & -\epsilon I
\end{bmatrix}
< 0, \quad Q > 0, \quad \epsilon > 0
$$
Thank you very much for your attention
